

# EXPERIMENT 4

## CONSOLIDATION TEST

---

**Purpose:**

This test is performed to determine the magnitude and rate of volume decrease that a laterally confined soil specimen undergoes when subjected to different vertical pressures. From the measured data, the consolidation curve (pressure-void ratio relationship) can be plotted. This data is useful in determining the compression index, the recompression index and the preconsolidation pressure (or maximum past pressure) of the soil. In addition, the data obtained can also be used to determine the coefficient of consolidation and the coefficient of secondary compression of the soil.

**Standard Reference:**

ASTM D 2435 - Standard Test Method for One-Dimensional Consolidation Properties of Soils.

**Significance:**

The consolidation properties determined from the consolidation test are used to estimate the magnitude and the rate of both primary and secondary consolidation settlement of a structure or an earthfill. Estimates of this type are of key importance in the design of engineered structures and the evaluation of their performance.

**Equipment:**

Consolidation device (including ring, porous stones, water reservoir, and load plate), Dial gauge (0.0001 inch = 1.0 div. on dial), Sample trimming device, glass plate, Metal straight edge, Clock, Moisture can, Filter paper.

***Geotechnical Engineering Laboratory Testing***  
***PROF. DR. SYED ABDUL MOFIZ***

**Geotechnical Engineering Laboratory Testing  
PROF. DR. SYED ABDUL MOFIZ**

**Test Procedure:**

- (1) Weigh the empty consolidation ring together with glass plate.
- (2) Measure the height ( $h$ ) of the ring and its inside diameter ( $d$ ).
- (3) Extrude the soil sample from the sampler, generally thin-walled Shelby tube. Determine the initial moisture content and the specific gravity of the soil. (Use the data sheets from these experiments to record all of the data).
- (4) Cut approximately a three-inch long sample. Place the sample on the consolidation ring and cut the sides of the sample to be approximately the same as the outside diameter of the ring. Rotate the ring and pare off the excess soil by means of the cutting tool so that the sample is reduced to the same inside diameter of the ring. It is important to keep the cutting tool in the correct horizontal position during this process.
- (5) As the trimming progresses, press the sample gently into the ring and continue until the sample protrudes a short distance through the bottom of the ring. Be careful throughout the trimming process to insure that there is no void space between the sample and the ring.
- (6) Turn the ring over carefully and remove the portion of the soil protruding above the ring. Using the metal straight edge, cut the soil surface flush with the surface of the ring. Remove the final portion with extreme care.

- (7) Place the previously weighed Saran-covered glass plate on the freshly cut surface, turn the ring over again, and carefully cut the other end in a similar manner.
- (8) Weigh the specimen plus ring plus glass plate.
- (9) Carefully remove the ring with specimen from the Saran-covered glass plate and peel the Saran from the specimen surface. Center the porous stones that have been soaking, on the top and bottom surfaces of the test specimen. Place the filter papers between porous stones and soil specimen. Press very lightly to make sure that the stones adhere to the sample. Lower the assembly carefully into the base of the water reservoir. Fill the water reservoir with water until the specimen is completely covered and saturated.
- (10) Being careful to prevent movement of the ring and porous stones, place the load plate centrally on the upper porous stone and adjust the loading device.
- (11) Adjust the dial gauge to a zero reading.
- (12) With the toggle switch in the down (closed) position, set the pressure gauge dial (based on calibration curve) to result in an applied pressure of 0.5 tsf (tons per square foot).
- (13) Simultaneously, open the valve (by quickly lifting the toggle switch to the up (open) position) and start the timing clock.

- (14) Record the consolidation dial readings at the elapsed times given on the data sheet.
- (15) Repeat Steps 11 to 13 for different preselected pressures (generally includes loading pressures of 1.0, 2.0, 4.0, 8.0, and 16.0 tsf and unloading pressures of 8.0, 4.0, 2.0, 1.0 and 0.5 tsf)
- (16) At the last elapsed time reading, record the final consolidation dial reading and time, release the load, and quickly disassemble the consolidation device and remove the specimen. Quickly but carefully blot the surfaces dry with paper toweling. (The specimen will tend to absorb water after the load is released.)
- (17) Place the specimen and ring on the Saran-covered glass plate and, once again, weigh them together.
- (18) Weigh an empty large moisture can and lid.
- (19) Carefully remove the specimen from the consolidation ring, being sure not to lose too much soil, and place the specimen in the previously weighed moisture can. Place the moisture can containing the specimen in the oven and let it dry for 12 to 18 hours.
- (20) Weigh the dry specimen in the moisture can.

**Analysis:**

- (1) Calculate the initial water content and specific gravity of the soil.

- (2) For each pressure increment, construct a semilog plot of the consolidation dial readings versus the log time (in minutes). Determine  $D_0$ ,  $D_{50}$ ,  $D_{100}$ , and the coefficient of consolidation ( $c_v$ ) using Casagrande's logarithm of time fitting method. See example data. Also calculate the coefficient of secondary compression based on these plots.
- (3) Calculate the void ratio at the end of primary consolidation for each pressure increment (see example data). Plot log pressure versus void ratio. Based on this plot, calculate compression index, recompression index and preconsolidation pressure (maximum past pressure).
- (4) Summarize and discuss the results.

**EXAMPLE DATA**

**Consolidation Test**  
**Data Sheets**

Date Tested: *October 05, 2002*

Tested By: *CEMM315 Class, Group A*

Project Name: *CEMM315 Lab*

Sample Number: *GB-08-ST-13'-15'*

Visual Classification: *Gray silty clay*

**Before test**

Consolidation type	= Floating type
Mass of the ring + glass plate	= 465.9 g
Inside diameter of the ring	= 6.3 cm
Height of specimen, $H_i$	= 2.7 cm
Area of specimen, $A$	= 31.172 cm <sup>2</sup>
Mass of specimen + ring	= 646.4 g
Initial moisture content of specimen, $w_i$ (%)	= 19.5 %
Specific gravity of solids, $G_s$	= 2.67

**After test**

Mass of wet sample + ring + glass plate	= 636.5 g
Mass of can	= 59.3 g
Mass of can + wet soil	= 229.8 g
Mass of wet specimen	= 170.50 g
Mass of can + dry soil	= 208.5 g
Mass of dry specimen, $M_s$	= 149.2 g
Final moisture content of specimen, $w_f$	= 14.27 %

### Calculations

Mass of solids in specimen,  $M_s$  =149.2 g  
 (Mass of dry specimen after test)

Mass of water in specimen before test,  $M_{wi}$  =  $w_i \times M_s$   
=  $0.195 \times 149.2 = 29.094$  g

Mass of water in specimen after test,  $M_{wf}$  (g) =  $w_f \times M_s$   
=  $0.1427 \times 149.2 = 21.29$  g

Height of solids,  $H_s = \frac{M_s}{A \times G_s \times \rho_w} = \frac{149.2}{31.172 \times 2.67 \times 1} = 1.792$  cm  
 (same before and after test and note  $\rho_w = 1$  g/cm<sup>3</sup>)

Height of water before test,  $H_{wi} = \frac{M_{wi}}{A \times \rho_w} = \frac{29.09}{31.172 \times 1} = 0.933$  cm

Height of water after test,  $H_{wf} = \frac{M_{wf}}{A \times \rho_w} = \frac{21.29}{31.172 \times 1} = 0.683$  cm

Change in height of specimen after test,  $\Sigma\Delta H$  =0.257 cm  
 ( $\Sigma\Delta H$  for all pressures – see t vs Dial Reading plots)

Height of specimen after test,  $H_f = H_i - \Sigma\Delta H = 2.7 - 0.257 = 2.443$  cm

Void ratio before test,  $e_o = \frac{H_i - H_s}{H_s} = \frac{2.7 - 1.792}{1.792} = 0.506$

Void ratio after test,  $e_f = \frac{H_f - H_s}{H_s} = \frac{2.443 - 1.792}{1.792} = 0.3617$

Degree of saturation before test,  $S_i = \frac{H_{wi}}{H_i - H_s} = \frac{0.933}{2.7 - 1.792} \times 100$   
=102.7 %

$$\text{Degree of saturation after test, } S_f = \frac{H_{wf}}{H_f - H_s} = \frac{0.683}{2.443 - 1.792} \times 100 \\ = 105.08\%$$

$$\text{Dry density before test, } \rho_d = \frac{M_s}{H_i \times A} = \frac{149.2}{2.7 \times 31.172} = 1.77 \text{ g/cm}^3 \\ = (110.6 \text{ pcf})$$

\*  $\Sigma \Delta H$  for applied pressure =  $\Sigma \Delta H$  of all previous pressures +  $\Delta H$  under applied pressure

$$** H_{dj} = \frac{H_j}{2} \pm \frac{\Delta H_j}{4} \quad \text{and} \quad H_j = H_i \pm \Delta H_{j-1} \quad (- \text{ for Loading and } + \text{ for Unloading})$$

$$*** C_v = 0.197 \times \frac{H_d^2}{t_{50}}, \quad H_v = (H_i - H_s) - \Sigma \Delta H \quad \text{and} \quad e = \frac{H_v}{H_s}$$

### Final Results:

Compression Index ( $C_c$ ) = 0.11

Recompression Index ( $C_r$ ) = 0.013

Preconsolidation pressure ( $P_c$ ) or Maximum past pressure ( $\sigma_{vmax}$ ) = 3.5 tsf

Coefficient of consolidation ( $C_v$ ) =  $1.54 \times 10^{-2}$  to  $9.01 \times 10^{-3}$  in<sup>2</sup>/min  
 (depends on the pressure)

Coefficient of secondary compression ( $C_\alpha$ ) = 0.001  
 (It is the slope of time vs settlement curve beyond the end of primary consolidation)
